CURRENT RESEARCH ACTIVITY:

Electromagnetics-of-nanostructures group exists in the Institute for Nuclear Problems since 1995. Electromagnetic response properties and electronic transport as well as linear and nonlinear optical phenomena in nanostructures are currently in the focus of the group activity. Several main topics can be singled out:

- Electromagnetic waves and signal propagation in nano-sized components and integrated nano-structured systems; electromagnetic compatibility problem on the nano scale.
- Electromagnetic response properties of composite materials with nano inclusions; electromagnetic shielding materials; nanocarbon in electromagnetic applications; nanocarbon based metamaterials.
- Ionizing radiation shielding materials; boron, boron nitride and chemically modified (doped) carbon nanotube-based composite materials;
- Nanocarbon in medical applications; far-infrared and terahertz range thermolysis of cancer cells.

A general approach is elaborated based on the interplay of present-day solid-state physics and classical methods of electrodynamics of inhomogeneous media. In particular,

- The method of effective boundary conditions has been extended to nanostructures and shown to be a universal tool for studying a wide range of problems of nanoelectrodynamics. The strong slowing down of surface waves in CNTs has been predicted, the concept of nanotubes as nanowaveguides of surface waves has been proposed (1999);
- The Mossotti-Clausius homogenization procedure for estimating the effective constitutive parameters of nanoparticle-based composite media, such as arrays of CNTs and QDs has been developed (1998, 2000).
- Polarisation-dependent splitting of the gain band in the QD array has been predicted and experimentally verified (in collaboration with A.F.Ioffe Physical-Technical Institute, St.Peterburg and Institut für Festkörperphysik, TU Berlin) (1999);
- The high-order harmonic generation by metallic CNTs exposed to an intense ultrashort pulse has been theoretically investigated. The strong nonlinearity of the laser interaction with CNTs has been predicted and confirmed experimentally (in collaboration with the Max-Born Institut fuer Nichtlineare Optik und Kurzzeitspektroskopie, Berlin) (2001-2006);
- The concept of excitonic composite has been introduced and local-field impact on quantum optics of isolated QDs and excitonic composites is under studying (1999-2007). It has been shown that the local fields induce a fine structure of the QD absorption (emission) spectrum (2002).

- The formalism of electrodynamics of lossy dispersive media has been applied to the problem of spontaneous radiation of an excited atom in the carbon nanotube demonstrating strong Parcell effect in CNTs (2002).
- The manifestation of local-field effect in Rabi oscillations of level population in QDs has been revealed (2003-2007)
- Wave scattering by an isolated finite-length CNT has been analysed. The potential of isolated CNTs as infrared and terahertz nanoantennas has been established. The analysis has been extended to CNT bundles and multi-wall CNTs. (2006 –);
- Thermal emission from CNTs has been investigated and a concept of CNT as a thermal nanoantenna has been proposed (2007);
- A concept of the CNT-based monomolecular light emitter — nanoscale traveling wave tube (TWT), backward oscillator (BWO) and free-electron laser (FEL) has been proposed. The calculations demonstrate that at the current stage of nanotechnology development the construction of CNT-based nanoFEL for terahertz frequency range is already possible (2006 –)
- Electromagnetic shielding properties of nano-carbon based composites in microwaves are currently under investigation both theoretically and experimentally, demonstrating promising high potential of OLC for the design of electromagnetic shielding materials over a broad microwave and terahertz frequency ranges (2006 –)
